# Summary

- 1 We know how to do simple t-tests.
- 2 We know how to fit simple linear models.

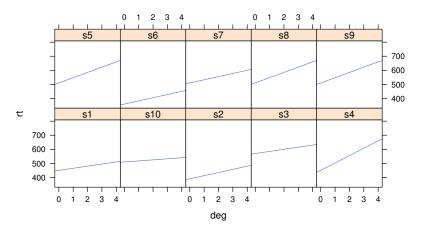

Now we are ready to look at an important type of linear model: linear mixed models.

Returning to our noise and deg data, one important point we've neglected is that different subjects have different effects of noise and deg. In the linear models we fit we were ignoring this.

We can visualize the different responses of subjects:

We can do the same for degree:

Given these differences between subjects, you could fit a separate linear model for each subject, collect together the intercepts and slopes for each subject, and then check if the intercepts and slopes are significantly different from zero.

Fit a separate model for one subject (s1):

```
## fit a separate linear model for subject s1:
s1data<-subset(noisedeg,subj=="s1")
m<-lm(rt~noise,s1data)
round(summary(m)$coefficients,digits=2)

## Estimate Std. Error t value Pr(>|t|)
## (Intercept) 420 42.43 9.9 0.01
## noisenoise 120 60.00 2.0 0.18
```

Look at the means for s1 for noise and compare them to the coefficients above.

Now we can do this for every one of our 10 subjects. I don't print this result out for space reasons.

There is a function in the package lme4 that does the above for you: lmList.

```
## do the same as the above for-loop for each subject:
library(lme4)

## Loading required package: Matrix
lmlist.fm1<-lmList(rt~noise|subj,noisedeg)</pre>
```

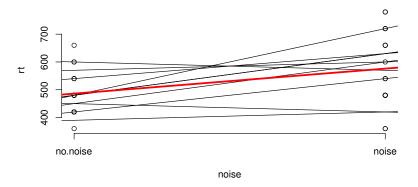

```
print(lmlist.fm1$s1)

##

## Call:
## lm(formula = formula, data = data)
##

## Coefficients:
## (Intercept) noisenoise
## 420 120
```

One can plot the individual lines for each subject, as well as the linear model m0's line (this shows how each subject deviates in intercept and slope from the model m0's intercept and slopes).

To find out if there is an effect of noise, you can simply check whether the slopes of the individual subjects' fitted lines taken together are significantly different from zero.

```
t.test(coef(lmlist.fm1)[2])
##
##
    One Sample t-test
##
## data: coef(lmlist.fm1)[2]
## t = 3.2225, df = 9, p-value = 0.01045
## alternative hypothesis: true mean is not equal to 0
## 95 percent confidence interval:
## 26.82139 153.17861
## sample estimates:
## mean of x
##
          90
```

The above is called **repeated measures regression**. We now transition to the next stage of multiple regression: the linear mixed model.

The **linear mixed model** does something related to the above by-subject fits, but with some crucial twists, as we see below. In the model shown in the next slide, the statement (1|subj)

means that the variance associated with subject intercepts should be estimated, and from that variance the intercepts for each subject should be predicted.

```
m0.lmer<-lmer(rt~noise+(1|subj),noisedeg)</pre>
```

#### Abbreviated output:

```
Random effects:
```

```
Groups Name Variance Std.Dev. subj (Intercept) 2491 49.91 Residual 8876 94.21 Number of obs: 40, groups: subj, 10
```

#### Fixed effects:

```
Estimate Std. Error t value
(Intercept) 486.00 26.32 18.463
noisenoise 90.00 29.79 3.021
```

One thing to notice is that the coefficients of the fixed effects of the above model are identical to those in the linear model m0 above.

The **predicted** (not estimated!) varying intercepts for each subject can be viewed by typing:

```
ranef(m0.lmer)
## $subj
       (Intercept)
##
## s1 -26.972985
## s10 -3.173292
## s2 -50.772677
## s3 36.492862
        12.693169
## s4
## s5 28.559631
## s6
       -66.639139
## s7
        12.693169
## s8
        28.559631
        28.559631
## s9
```

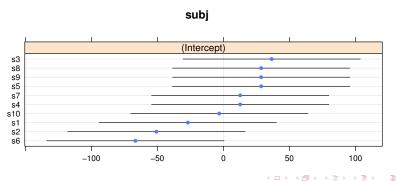

```
Lecture 4

Linear mixed models

Varying intercepts models
```

Or you can display them graphically.

```
print(dotplot(ranef(m0.lmer,condVar=TRUE)))
## $subj
```

The model m0.lmer above prints out the following type of linear model:

$$Y_{ijk} = \beta_j + b_i + \epsilon_{ijk} \tag{1}$$

 $i=1,\ldots,10$  is subject id, j=1,2 is the factor level (no noise or noise), k is the number of replicates (here 1).  $b_i \sim N(0,\sigma_b^2), \epsilon_{iik} \sim N(0,\sigma^2).$ 

It's just like our linear model except that there are different predicted (cf. the Imlist function above, where they are estimated for each subject) intercepts  $b_i$  for each subject.

Note that these  $b_i$  are assumed by Imer to come from a normal distribution centered around 0; see Gelman and Hill 2007 for more. The ordinary linear model m0 has one intercept  $\beta_0$  for all subjects, whereas the linear mixed model with varying intercepts m0.Imer has a different intercept  $(\beta_0 + b_i)$  for each subject. We can visualize these different intercepts for each subject as shown below.

```
## (Intercept)
##
          486
      (Intercept)
##
## s1 459.0270
## s10 482.8267
## s2 435.2273
## s3 522,4929
## s4 498.6932
## s5
         514.5596
## s6
         419.3609
## s7
        498.6932
         514.5596
## s8
         514.5596
## s9
```

Note that, unlike the figure associated with the lmlist.fm1 model above, which also involves fitting separate models for each subject, the model m0.lmer assumes different intercepts for each subject but the same slope.

We can have Imer fit different intercepts AND slopes for each subject.

```
m1.lmer<-lmer(rt~noise+(1+noise|subj),noisedeg)</pre>
```

#### Random effects:

	Groups	Name	Variance	Std.Dev.	Corr
	subj	(Intercept)	1093	33.05	
		noisenoise	1408	37.52	1.00
	Residual		8359	91.43	
]	Number of	obs: 40, gro	oups: sul	oj, 10	

#### Fixed effects:

	Estimate Std.	Error t	value
(Intercept)	486.00	22.96	21.17
noisenoise	90.00	31.25	2.88

└─Varying intercepts and slopes model

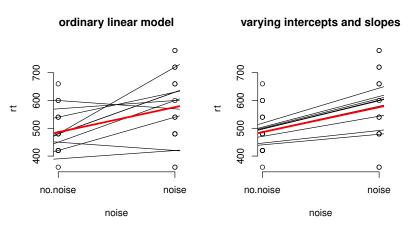

#### Linear mixed models

These fits for each subject are visualized below (the red line shows the model with a single intercept and slope, i.e., our old model m0):

#### varying intercepts and slopes for each subject

Compare this model with the lmlist.fm1 model we fitted earlier:

- 1 The above graphic shows some crucial difference between the Imlist (repeated measures) model and the Imer model.
  - 2 Note that the fitted line for each subject in the Imer model is much closer to the m0 model's fitted (red) line.
- This is because Imlist uses each subject's data separately (resulting in possibly wildly different models, depending on the variability between subjects), whereas Imer "borrows strength from the mean" and pushes (or "shrinks") the estimated intercepts and slopes of each subject closer to the mean intercepts and slopes (the model m0's intercepts and slopes).
- Because it shrinks the coefficients towards the means, this is called shrinkage. This is particularly useful when several data points are missing in a particular condition for a particular subject: in an ordinary linear model, estimating coefficients using lmList would lead to very poor estimates for that subject; by contrast, lmer assumes that the estimates for such a subject are not reliable and therefore shrinks that subject's estimate to the mean values.

To see an example of shrinkage, consider the case where we remove three of the data points from subject s8, resulting in exaggeratedly high means for that subject.

First, we read in a data frame which is just the same as noisedeg, except that subject 8 (s8) has only three data points, not six (I took out three of s8's low measures). This skews the subject's estimates for intercept and slope in the Imlist model fit.

I am now using the full noisedeg dataset (this is a 2x3 design, with three levels of degree, 0, 4, 8).

```
noisedeg2<-read.table("data/noisedegfull.txt",header=T)</pre>
```

Next, let's confirm that the new data frame has extreme means for s8.

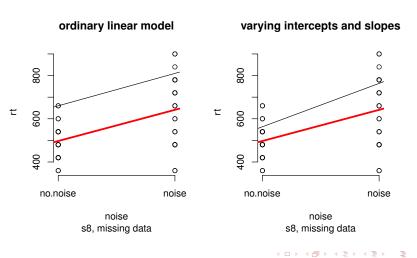

```
with(noisedeg,tapply(rt,list(subj,noise),mean,na.rm=TRUE))
##
       no.noise noise
## s1
            420
                  540
            450 600
## s10
## s2
            450 420
                  720
## s3
            480
            480
                  630
## s4
            600
                  570
## s5
                  420
## s6
            390
            480
                  630
## s7
## s8
            540
                  630
            570
                  600
## s9
```

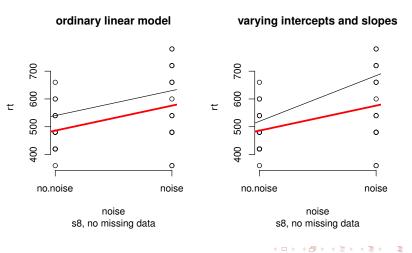

```
with(noisedeg2,tapply(rt,list(subj,noise),mean,na.rm=TRUE))
       no.noise noise
##
## s1
            440
                  620
            480 660
## s10
## s2
            460 480
            500
## s3
                  740
            500
                  720
## s4
            580
                  620
## s5
## s6
                  460
            380
            520
                  700
## s7
## s8
            660
                  810
            560
                  660
## s9
```

We now fit the Imlist model and the linear mixed model.

```
lmlist.fm2<-lmList(rt~noise|subj,noisedeg2)
m2.lmer<-lmer(rt~noise+(1+noise|subj),noisedeg2)</pre>
```

Now if we plot the model for s8, we find that the Imlist model indeed estimates **pretty extreme intercepts for s8**. But the linear mixed model predicts an intercept that's **much closer to the mean** (the red line). Let's just plot s8's fitted line in both models relative to the linear model fitted line.

#### Linear mixed models

One crucial difference between the Imlist model and the Imer model is that ImList estimates the parameters for each subject separately.

By contrast, **Imer estimates the variance associated with subjects' intercepts** (and slopes, if you specify in the model that one should do that) and then *predicts* each subjects intercepts and slopes based on that variance.

I will formalize this on the last day if there is time.

Processing Chinese relative clauses in context

Research question: Are subject relatives harder than object relatives in Chinese?

```
data<-read.table("data/gibsonwu2012data.txt",header=TRUE)</pre>
headnoun <- subset (data, region == "headnoun")
head(headnoun[,c(1,2,3,7)])
##
       subj item
                    type
                            rt
## 94
              13 obj-ext 1561
## 221 1
               6 subj-ext
                           959
               5 obj-ext
                           582
## 341
## 461
                  obj-ext 294
              14 subj-ext
                           438
## 621
## 753
               4 subj-ext
                           286
```

1 U Z 1 DZ Z 1 E Z 1 E Z 1

Processing Chinese relative clauses in context

Published result was approximately the following (statistically significant):

```
contrasts(data$type) <-contr.sum(2)
contrasts(data$type)

## [,1]
## obj-ext 1
## subj-ext -1</pre>
```

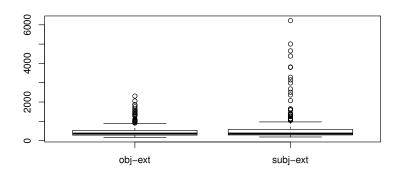

Processing Chinese relative clauses in context

```
m0<-lmer(rt~type+(1+type|subj)+(1|item),headnoun)
summary(m0)$coefficients

## Estimate Std. Error t value
## (Intercept) 487.6670 52.37682 9.310741
## typesubj-ext 120.3888 56.86962 2.116926
```

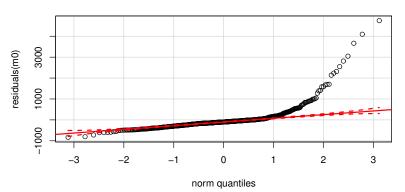

Processing Chinese relative clauses in context

Result is driven by 1% of extreme values:

Processing Chinese relative clauses in context

Residuals are severely non-normal:

Processing Chinese relative clauses in context

With a log transform of reading time (to reduce influence of extreme values; see Box and Cox 1964), we see no evidence for an effect (inconclusive result):

```
m1<-lmer(log(rt)~type+(1+type|subj)+(1|item),headnoun)
summary(m1)$coefficients

## Estimate Std. Error t value
## (Intercept) 6.02554797 0.06404223 94.08710
## typesubj-ext 0.07249477 0.04830504 1.50077</pre>
```

Varying intercepts model

The model for a categorical predictor is:

$$Y_{ijk} = \beta_j + b_i + \epsilon_{ijk} \tag{2}$$

 $i=1,\ldots,10$  is subject id, j=1,2 is the factor level, k is the number of replicates (here 1).  $b_i \sim N(0,\sigma_b^2), \epsilon_{ijk} \sim N(0,\sigma^2)$ .

Varying intercepts model

For a continuous predictor:

$$Y_{ijk} = \beta_0 + \beta_1 t_{ijk} + b_{ij} + \epsilon_{ijk}$$
 (3)

Varying intercepts and varying slopes model

The model for a categorical predictor is:

$$Y_{ij} = \beta_1 + b_{1i} + (\beta_2 + b_{2i})x_{ij} + \epsilon_{ij}$$
  $i = 1, ..., M, j = 1, ..., n_i$  (4)

with  $b_{1i} \sim N(0, \sigma_1^2)$ ,  $b_{2i} \sim N(0, \sigma_2^2)$ , and  $\epsilon_{ij} \sim N(0, \sigma^2)$ .

Varying intercepts and varying slopes model

Another way to write such models is:

$$Y_{ijk} = \beta_j + b_{ij} + \epsilon_{ijk} \tag{5}$$

 $b_{ij} \sim N(0, \sigma_b)$ . The variance  $\sigma_b$  must be a 2 × 2 matrix:

$$\begin{pmatrix} \sigma_1^2 & \rho \sigma_1 \sigma_2 \\ \rho \sigma_1 \sigma_2 & \sigma_2^2 \end{pmatrix} \tag{6}$$

See my linear modeling notes for much more.
